

Methodological Caveats and Limitations

Overdispersion

The quasibinomial models show dispersion parameters of 7–9, indicating substantial overdispersion relative to the binomial assumption. This is expected for aggregate vote data (voters within precincts are not independent), and the quasibinomial family corrects standard errors accordingly. However, the magnitude suggests that precinct-level unobserved heterogeneity is large. The GLMM with random intercepts by locale captures some of this, but within-locale heterogeneity remains.
